ADAPTIVE BLIND EQUALIZATION OF SIMO SYSTEMS
BASED ON CANONICAL CORRELATION ANALYSIS

ABSTRACT
In this work we consider the problem of blind equalization of single-input multiple-output systems (SIMO), which is formulated as a Canonical Correlation Analysis (CCA) problem. CCA is a classical tool in statistical analysis that measures the linear relationship between two or several data sets, and, in previous works, we have shown that CCA can be reformulated as a set of coupled least squares regression problems, which allows us to derive in a straightforward manner a recursive least squares (RLS) algorithm for on-line CCA. This algorithm can be directly applied to the blind equalization problem or easily modified to obtain a Soft Decision Feedback Equalizer (SDFE). Some simulation results show that the CCA-based algorithms outperform other blind equalization techniques based on second-order statistics.

1. INTRODUCTION
Blind identification of single-input multiple-output (SIMO) channels is a common problem encountered in communications, sonar and seismic signal processing. SIMO channels appear either when the signal is oversampled at the receiver or from the use of an array of antennas. It is well known that, if the input signal is informative enough and the FIR channels are co-prime, second order statistics are sufficient for blind equalization. The most popular SOS-based approach for blind equalization is the Modified Second Order Statistics Algorithm (MSOSA) [1]. A drawback of this method is its bad performance for ill-conditioned channels or its noise-enhancement effect for strongly colored signals.

In this paper we consider the application of Canonical Correlation Analysis (CCA) to blind equalization of SIMO channels. CCA is a well-known technique in multivariate statistical analysis, which has been widely used in economics, meteorology, and in many modern information processing fields, such as communication theory, statistical signal processing, and Blind Source Separation (BSS).

CCA was developed by H. Hotelling [2] as a way of measuring the linear relationship between two multidimensional sets of variables and was later extended to several data sets [3]. Recently, the reformulation of CCA as a set of LS regression problems was exploited to derive an on-line CCA algorithm [4]. Here, we show that maximizing the correlation among the outputs of the equalizers (i.e. CCA) is a reasonable equalization criterion, which outperforms other blind equalization techniques such as the MSOSA.

Finally, the adaptive blind equalization algorithm is modified in a straightforward manner to obtain a Soft Decision Feedback Equalizer (SDFE) and some simulation results show the performance of the different adaptive blind equalization algorithms.

2. PROBLEM FORMULATION
Suppose the system shown in Fig. 1, where \( s[n] \) is a source signal which is sent through \( K \) different finite impulse response (FIR) channels satisfying the length-and-zero condition:

**Condition 1 (Length and zero)** Let \( K \) FIR channels of length \( L \) satisfy the length-and-zero condition if:

1. \( h_k[0] \neq 0 \) and \( h_i[L-1] \neq 0 \) for some \( 1 \leq k, l \leq K \).
2. The \( K \) channels are coprime, i.e. they do not share any common zeros.

The observation vector \( \mathbf{x}_r[n] = [x_1[n], \ldots, x_K[n]]^T \) can be written as

\[
\mathbf{x}_r[n] = \mathbf{h}[n] * s[n],
\]

or in matrix form

\[
\mathbf{x}[n] = \mathbf{H}\mathbf{s}_{L\times K}[n], \quad \text{or} \quad \mathbf{X}[n] = \mathbf{H}\mathbf{S}_{L\times K}[n], \quad (1)
\]
where we have used the following definitions

\[ h[n] = [h_1[n], \ldots, h_K[n]]^T, \]
\[ H = \begin{bmatrix} h[0] & \cdots & h[L-1] & \cdots & 0 \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & \cdots & h[0] & \cdots & h[L-1] \end{bmatrix}, \]
\[ s_{L_k}[n] = [s[n], \ldots, s[n - L_k - L + 2]]^T, \]
\[ x[n] = \begin{bmatrix} x_1[n] \\ \vdots \\ x_L[n] \end{bmatrix}, \]
\[ S_{L_k}[n] = [s_{L_k}[n], \ldots, s_{L_k}[n + N - 1]], \]
\[ X[n] = [x[n], \ldots, x[n + N - 1]], \]

and where \( L_{eq} \) is a parameter determining the dimensions of the vectors and matrices, and satisfying the equalizer length condition

**Condition 2 (Equalizer length)** The parameter \( L_{eq} \) satisfies the equalizer length condition iff

\[ L_{eq} \geq \frac{L - 1}{K - 1}. \]

Based on conditions 1 and 2, it is easy to prove that \( H \) is a full column rank matrix with \( M = L_{eq} + L - 1 \) columns. Hence, from (1), there exists a matrix \( W = [w_1, \ldots, w_M] \), of dimensions \( KL_{eq} \times M \), such that

\[ s_{L_k}[n] = W^H x[n], \]

and then, for \( k, l = 1, \ldots, M \) and every integer \( n \) we have

\[ w_k^H x[n + k] = w_k^H x[n + l]. \]

Further, it has been proved in [5] that, if the channel satisfies the length-and-zero condition and the channel input is \((L_{eq} + 1)\)-th order persistently exciting, i.e. the linear complexity [6] of the source signal is \( C(s[n]) \geq L_{eq} + L \),

**Condition 3 (Persistently exciting)** A sequence \( s[n] \) is said to be \((L_{eq} + 1)\)-th order persistently exciting iff \( S_{L_{eq} + 1}[n] \) is of full row rank for some \( N \).

then the equalizers \( w_k \) ’s satisfying (2) will satisfy

\[ W^H H = c I, \]

where \( c \) is some nonzero constant. Then we can use (2) to solve the equalization problem, and considering the channel noise, the estimated signals can be defined, for \( k = 1, \ldots, M \), as

\[ \hat{s}_k[n] = w_k^H x[n + k - 1]; \quad \hat{s}_k = w_k^H X[n + k - 1], \]

and the final estimated signal is obtained as

\[ \hat{s} = \frac{1}{M} \sum_{k=1}^{M} \hat{s}_k. \]

**3. MSOSA PROCEDURE**

In [1], the authors derive the modified second-order statistics based algorithm (MSOSA), which is based on the minimization of the following cost function

\[ J_{MSOSA} = \sum_{k,l=1}^{M} E [\hat{s}_k[n] - \hat{s}_l[n]]^2. \]

subject to certain nontrivial restrictions. Applying a gradient based procedure, the MSOSA update rules are

\[ w(n + 1) = w(n) + \mu \hat{R}(n + 1)w(n), \]

\[ \alpha(n + 1) = \left( \sum_{k=1}^{L_{eq} + L - 1} \hat{w}_k^H (n + 1) \hat{R}_0(n + 1) \hat{w}_k(n + 1) \right)^{\frac{1}{2}}, \]

where \( \hat{w}(n) = [\hat{w}_1^T(n), \ldots, \hat{w}_M^T(n)] \), \( \mu \) is a stepsize, \( c \) is some nonzero constant, and the shifted correlation matrices are estimated as

\[ \hat{R}_k(n + 1) = \lambda \hat{R}_k(n) + (1 - \lambda) x[n - k] x^H[n], \]

where \( 0 \leq \lambda \leq 1 \) is a forgetting factor and the composite matrix \( \hat{R}(n) \) is

\[ \hat{R}(n) = \begin{bmatrix} (M - 1) \hat{R}_0(n) & -\hat{R}_1(n) & \cdots & -\hat{R}_{M-1}(n) \\ -\hat{R}_1(n) & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ -\hat{R}_{M-1}(n) & \cdots & (M - 1) \hat{R}_0(n) \end{bmatrix}. \]

From the above definitions it is easy to prove that the MSOSA procedure is equivalent to the well-known power method to extract the main eigenvector and eigenvalue of \( \hat{R}(n) \), which is the solution of the problem of minimizing (4) subject to \( ||w(n)|| = c \). Furthermore, this solution is closely related to Principal Component Analysis (PCA) and the channel estimation technique proposed in [6].

Finally, a related algorithm is proposed in [7], which can be interpreted as a two steps algorithm based on the MSOSA solution. In the first step the MSOSA solution is obtained, and then, the \( M \) equalized signals are linearly combined, using some optimality criterion (instead of (3)), to form the final estimated signal.

**4. CCA PROCEDURE**

**4.1. Proposed Cost Function**

The proposed cost function is based on the generalization to \( M > 2 \) data sets of the canonical correlation analysis (CCA) problem proposed in [4], which can be interpreted as the problem of finding the \( M \) equalizers \( w_k \) providing the maximum correlated estimated signals \( \hat{s}_k \), i.e. defining \( \tilde{R}_k = X[n + k - 1] X^H[n + l - 1] \), we will try to maximize the coefficient

\[ \beta = \frac{1}{M^2} \sum_{k,l=1}^{M} \hat{s}_k \hat{s}_l^H = \frac{1}{M^2} \sum_{k,l=1}^{M} \hat{s}_k \hat{s}_l^H \hat{R}_{kl} w_l. \]
subject to the following restriction
\[
\frac{1}{M} \sum_{k=1}^{M} \| \mathbf{s}_k \|^2 = c,
\]
which is used to avoid the trivial solution. Furthermore, this restriction makes the CCA problem in (5) equivalent to minimize \(\sum_{k=1}^{M} \| \mathbf{s}_k - \hat{\mathbf{s}}_k \|^2\), and then, the CCA problem can be interpreted as the deterministic version of the MSOSA problem with a different nontrivial restriction. This new restriction in the energy of the outputs of the equalizers produces a mitigation of the noise enhancement problem for colored signals.

Using matrix notation, the CCA problem (5) can be formulated as
\[
\arg\max_{\mathbf{w}} \beta = \frac{1}{M^2} \mathbf{w}^H \mathbf{R} \mathbf{w} \text{ s.t. } \frac{1}{M} \mathbf{w}^H \mathbf{D} \mathbf{w} = c,
\]
where
\[
\mathbf{R} = \begin{bmatrix}
\mathbf{R}_{11} & \cdots & \mathbf{R}_{1M} \\
\vdots & \ddots & \vdots \\
\mathbf{R}_{M1} & \cdots & \mathbf{R}_{MM}
\end{bmatrix}; \quad \mathbf{D} = \begin{bmatrix}
\mathbf{1} & \mathbf{0} \\
\mathbf{0} & \mathbf{R}_{11} & \cdots & \mathbf{0} \\
\vdots & \vdots & \ddots & \vdots \\
\mathbf{0} & \mathbf{R}_{M1} & \cdots & \mathbf{R}_{MM}
\end{bmatrix}.
\]

The solution of (7) is obtained using the method of Lagrange multipliers, which reduces the CCA problem to find the eigenvector associated to the maximum eigenvalue of the following generalized eigenvalue problem (GED)
\[
\frac{1}{M} \mathbf{R} \mathbf{w} = \beta \mathbf{D} \mathbf{w}.
\]

From the definition in (8) and the structure of \(\mathbf{R}\) and \(\mathbf{D}\), we can obtain \(\beta \mathbf{w}_k\), for \(k = 1, \ldots, M\) as the solution of the following least squares (LS) regression problems
\[
J_{\text{LS}}(\beta \mathbf{w}_k) = \| \mathbf{X}^H [n + k - 1] \beta \mathbf{w}_k - \hat{\mathbf{s}}_k \|^2,
\]
and these solutions can be obtained iteratively using the technique proposed in [4].

4.2. Adaptive CCA Solution

The adaptive CCA algorithm proposed in [4] is based on the application of the recursive least squares (RLS) algorithm to the LS problems defined in (9). Furthermore, the fact that all CCA data sets are delayed versions of \(\mathbf{X}[n]\) allows a reduction in the computational complexity due to the calculation of only one (instead of \(M\)) set of RLS parameters

\[
k(n) = \frac{\mathbf{P}(n-1) \mathbf{x}[n]}{\lambda + \mathbf{x}^H [n] \mathbf{P}(n-1) \mathbf{x}[n]},
\]

\[
\mathbf{P}(n) = \frac{\mathbf{P}(n-1) - \mathbf{k}(n) \mathbf{x}^H [n] \mathbf{P}(n-1)}{\lambda}
\]

These RLS parameters are
\[
k(n) = \frac{\mathbf{P}(n-1) \mathbf{x}[n]}{\lambda + \mathbf{x}^H [n] \mathbf{P}(n-1) \mathbf{x}[n]},
\]

\[
\mathbf{P}(n) = \frac{\mathbf{P}(n-1) - \mathbf{k}(n) \mathbf{x}^H [n] \mathbf{P}(n-1)}{\lambda}
\]

where \(\mathbf{P}(n)\) is the inverse of the correlation matrix
\[
\Phi(n) = \sum_{l=0}^{n} \lambda^{n-l} \mathbf{x}[l] \mathbf{x}^H [l] = \frac{\mathbf{R}_0(n)}{1 - \lambda},
\]

and \(\mathbf{k}(n)\) is the Kalman gain vector of the process \(\mathbf{x}[n]\). The adaptive CCA update equation can be written as
\[
\mathbf{K}(n) = \begin{bmatrix}
\mathbf{k}(n - M + 1) & \cdots & \mathbf{0} \\
\vdots & \ddots & \vdots \\
\mathbf{0} & \cdots & \mathbf{k}(n)
\end{bmatrix},
\]

and \(\mathbf{e}[n] = [e_1[n], \ldots, e_M[n]]^H\), with
\[
e_k[n] = \hat{s}_k[n - M + 1] - \beta(n-1) \hat{s}_k[n - M + 1],
\]

and \(\hat{s}_k[n - M + 1] = \mathbf{w}_k^H (n-1) \mathbf{x}[n - M + k]\).

The overall adaptive CCA algorithm for blind equalization of SIMO channels is closely related to the fixed-point algorithm for generalized eigendecomposition (GED) proposed in [8]. However, it is interesting to point out that our method is a true RLS algorithm, which uses a reference signal specifically constructed for CCA. This reference signal can be used, for instance, to develop a robust version of the algorithm [9] or to implement a Soft Decision Feedback Equalizer.

4.3. Soft Decision Feedback Equalizer

Frequently, blind equalization problems can make use of known properties of the transmitted signal, such as its pdf, spectral properties or higher order statistics. This is the case in communication problems, where the knowledge of the constellation symbols can...
be used to obtain a Soft Decision Feedback Equalizer (SDFE) [10]. The proposed adaptive CCA algorithm can be easily modified to obtain a SDFE in the following way

\[ e_n[n] = f_{n-1}(\delta[n-M+1]) - \beta(n-1)\delta[n-M+1], \]

where \( f_{n}(\cdot) \) tries to make the objective signal closer to the source signal. Working with QAM constellations, and ignoring the inde-terminacy in phase and energy (which can be solved by means of a phase recovery algorithm [11] and an energy normalization step), we can write

\[ f_n(\cdot) = g_n(\Re(\cdot)) + jg_n(\Im(\cdot)), \]

where \( \Re(\cdot) \) and \( \Im(\cdot) \) denotes the real and imaginary part, respectively, and \( g_n(\cdot) \) can be selected as

\[ g_n(y) = y_{th} + \frac{d_S}{2} \tan^{-1} \frac{d_S(y-y_{th})}{2\sigma^2(n)}, \tag{13} \]

where \( y_{th} \) denotes the mid-point between the two closer symbols, \( d_S \) is the distance between contiguous symbols and \( \sigma^2(n) \) is the estimated noise energy after equalization

\[ \sigma^2(n) = \frac{1 - \lambda}{M} \sum_{l=0}^{n} \lambda^{n-l} \| e[l] \|^2, \]

which can be sequentially updated by means of the well-known RLS equations. The function defined in (13) can be interpreted as a bias-corrected version of the MMSE estimator [12], and it is equivalent to \( g_n(y) \approx y \) for high noise situations, whereas \( g_n(y) \) match the MMSE estimator for low noise situations. In the limiting cases, \( g_n(y) = y \) for \( \sigma^2(n) = \infty \) and \( g_n(y) \) is a hard decision function for \( \sigma^2(n) = 0 \). Finally, the CCA-based SDFE is resumed in Algorithm 1

\[ 5. \text{SIMULATION RESULTS} \]

In this section the performance of the proposed algorithm is evaluated in terms of intersymbol interference (ISI). The composite channel-equalizer impulse response \( c = [c[1], \ldots, c[2M-1]] \)

Fig. 2. Performance of the Batch algorithms for different data set sizes.

Fig. 3. Convergence of the adaptive algorithms in the example proposed by Li and Liu. \( \lambda = 0.9 \).

can be obtained from the sum of the diagonals of \( C = \mathbf{W}^H \mathbf{H} \), and the ISI can be defined as

\[ ISI = 10 \log_{10} \frac{\| [e] \|^2 - |c[M]|^2}{|c[M]|^2}. \]

In all the simulations the results of 300 independent realizations are averaged, where the source signals are 16-QAM, the received signals are corrupted by zero-mean white, Gaussian noise, and the selected “length” of the equalizer is \( L_{eq} = (L-1)/(K-1) \). Finally, the initialization parameters are

- \( P(0) = 10^7 \mathbf{I} \), \( \beta(0) = 0 \) and \( \sigma(0) = 10^2 \).
- \( w_k(0) \), for \( k = 1, \ldots, M \), are initialized as random vectors.

5.1. Batch Performance

Here the performance of the CCA and MSOSA Batch algorithms is evaluated as a function of the size of the data sets, the channel impulse responses are those proposed in [1], i.e. [0.6662 – j0.8427, 1.6323 – j0.2503, –0.6617 – j0.4102] and [0.4607 + j0.5789, 0.5855 – j0.6912, 1.3273 – j0.4184]. The simulation results are shown in figure 2, where the improvement of the CCA method for small data sets is illustrated.

5.2. Online Performance

Here two different examples are presented. The first one is the example proposed in [1], where the observations are corrupted with two different SNR levels. The forgetting factor is \( \lambda = 0.9 \) and the results are shown in figure 3, where we can see the faster convergence of the CCA-RLS algorithm.

In the second example the performance of the adaptive algorithms for a different SIMO channel is evaluated. The signal to noise ratio is \( \text{SNR}=30 \text{dB} \) and the forgetting factor is \( \lambda = 0.95 \). The impulse response of the SIMO channel is shown in table 1 and the results can be seen in figure 4. As we can see, the CCA advantage is increased with the channel complexity and the soft decision feedback equalizer implies a faster convergence and a lower final ISI. Finally, figure 5 shows the SDFE function in four different temporal points.
In this paper, the generalization to several data sets of the CCA problem, and a new RLS based algorithm for adaptive CCA have been applied to the blind equalization of SIMO channels. The realization of multiple-input multiple-output (MIMO) channels and the problem, and a new RLS based algorithm for adaptive CCA have been exploited to develop a soft decision feedback equalizer. The performance of the algorithm has been demonstrated through simulations in blind SIMO channel equalization problems, where the adaptive algorithm outperforms other blind equalization techniques based on second order statistics. Further investigation lines include the application of the proposed method to blind equalization of multiple-input multiple-output (MIMO) channels and the extension of the proposed method to kernel CCA (KCCA) or non-linear equalization.

6. CONCLUSIONS

In this paper, the generalization to several data sets of the CCA problem, and a new RLS based algorithm for adaptive CCA have been applied to the blind equalization of SIMO channels. The formulation of CCA as a set of coupled LS regression problems has been exploited to develop a soft decision feedback equalizer. The performance of the algorithm has been demonstrated through simulations in blind SIMO channel equalization problems, where the adaptive algorithm outperforms other blind equalization techniques based on second order statistics. Further investigation lines include the application of the proposed method to blind equalization of multiple-input multiple-output (MIMO) channels and the extension of the proposed method to kernel CCA (KCCA) or non-linear equalization.
